steps for 7: click start, click control panel, and then double-click add a program. in the search box, type device manager and then click ok. in device manager, click expand to expand the view menu to more views, and then click show hidden devices. in device manager, click the + button on the right side of the drivers tab. from the drop-down menu, select unknown devices and then click ok. in device manager, right-click the unknown device, and then click update driver. browse your computer for the appropriate driver. hid input devices use various hardware protocols, such as i2c, m-bus, smbus, infrared, rs232, and usb, to send reports. usb is the most common transport, but other transports are available in some cases. here is a complete list of the technologies for connecting to a hid device. if you're in windows 7 or later and you want to connect to a usb device, then installing the appropriate driver is the first step. the following diagram shows the steps you can use to connect to a usb device from device manager. so my only real point of it is there, not something you would really want to be using on a consistent basis. it's a cool little device. great size and range of options for the kind of touch input you can get but just no stability. still having issues. i just can't figure it out. i thought maybe it was somehow related to the health of the battery, so i replaced it and have yet to get the same issues. i have tried a few times with a new battery, other touch-screen options and every thing i can find on the internet to no avail. there are more people complaining about it than i've ever seen of any of the other models. needless to say i will try other options as well as help others through my own research, but for now, i am stuck and i am beginning to think it is not only my inexperience with the other touch options but also an issue with that particular model of touch screen.

i connected my wintab to my pc, powered on and restarted the tablet. i then tested various touch points on the screen; and the screen responds as i'd expect it to. i wouldn't describe the touchscreen's performance as perfect (there's a slight delay from when my finger touches the screen and it registering with the app), but for a device that costs \$299, i'm honestly happy with it. i've put a breakpoint in the kernel and traced the hit registers as my finger touches and moves around the screen. what i found was interesting; the top-level and sub-collections seemed to behave as i'd expect, but the sub-sub-collections weren't consistent at all and the minidriver appeared to be inverting my selections on me (from the point of view of the device). my next experiment was to load the silead driver and run the same application. lo and behold, the drivers register the touch as expected. it doesn't appear to be inverting the input data, if that makes sense. the first thing i did was to unplug the usb otg adapter and power down my device. i then connected the wintab to the pc using the provided micro usb cable. i then installed and ran the goodix driver, and it all worked perfectly. i then tried unplugging the cable and powering down the wintab; only this time i used the silead driver. i then tried plugging in the micro usb adapter to my pc and installing and running the silead driver; the wintab appeared to lose its wifi connection and rebooted, with the screen displaying only a blinking cursor. the touch display was read-only. i then removed the usb adapter and restarted; and the touchscreen became read-only again. i'm not entirely sure why this happens or what the consequences of it is - maybe something to do with optimising the usb otg power usage? 5ec8ef588b
